UCT Part Number

LPFLTR01LipiFiltr® push-through cartridge

Summary:

Cannabis testing laboratories face the difficult task of removing a variety of unwanted matrix components from their samples prior to LC-MS or GC-MS analysis. High-lipid samples, in particular, pose a major challenge when testing for a large number of pesticide residues that contain different physicochemical properties and need to be detected at very low concentrations. Oil-based cannabis products often use a variety of food grade oils such as medium chain triglyceride oil, coconut oil, olive oil and hemp oil, and the complexity of these cannabis products presents additional analytical challenges that do not need to be accounted for in other laboratory settings. Typical sample preparation procedures, such as QuEChERS, are easy to carry out and wellsuited for the extraction of a wide range of pesticide residues. However, they also extract a large amount of matrix components, including lipids and other hydrophobic compounds, which can lead to poor analyte recovery and reproducibility, chromatographic interference, ion suppression/enhancement, and additional instrument maintenance. Current sample cleanup options may not be suitable for effectively and selectively removing these unwanted interferences. Large amounts of lipids remaining in the sample may then necessitate the use of additional cleanup steps or the use of a product that will indiscriminately retain lipids and analytes of interest. To overcome these challenges UCT recently introduced a new product for the cleanup of fatty samples – LipiFiltr®. The ability to obtain significantly cleaner extracts, ease of use, and time and cost savings make the new LipiFiltr® push-thru cartridges are an attractive cleanup option for laboratories conducting pesticide residue analysis in complex fatty samples.

This application note outlines the performance benefits achieved using the LipiFiltr® cleanup cartridge for the analysis of pesticides in oil-based cannabis products using LC-MS/MS analysis. The pesticides evaluated in this study include those listed in the Oregon monitoring list (≈60 pesticides). CBD oil was used as the representative matrix. A comparison of pre- and post-LipiFiltr® cleanup using full scan GC-MS is also presented to demonstrate the removal of lipid coextractives. This work was originally presented as a poster at the North American Chemical Residue Workshop (NACRW) 2018 in Naples, Florida.

Procedure:

- 1. Weigh 1 g of sample into a 50 mL polypropylene centrifuge tube.
- 2. Add internal standard(s).
- 3. Add 10 mL of extraction solvent (acetonitrile/water/toluene, 90/5/5, v/v).
- 4. Shake or vortex the sample for 1 hour.
- 5. Centrifuge the sample at \geq 1500 rcf for 5 minutes.
- 6. Pass 1.5 mL supernatant through a LipiFiltr® cartridge and collect the purified extract in an autosampler vial.

Results:

Coextractives Removal

A comparison of pre and post LipiFiltr® cleanup was evaluated using a generic GC-MS full scan acquisition. All samples were run on a Rxi-5Sil MS column (30m x $0.25 \mu m$) with a Topaz Precision split inlet liner. A 1 μL injection volume with a split ratio of 10:1 was used.

Pesticide Recovery

A single matrix-matched calibration point (200 ppb) was used to calculate the recoveries (n=5). Linuron-d6 was utilized as the internal standard. The mass spectrometer used for analysis was a SCIEX Triple Quad 6500+ using the SCIEX vMethodTM for Pesticides in Cannabis. The ion ratio acceptance criteria was set at \pm 30% (relative).

Discussion:

Several combinations of solvents were evaluated to find the best extraction solution for the wide range of pesticides included in the method, including acetonitrile/methanol (90/10, v/v), acetonitrile/IPA (80/20, v/v) and acetonitrile/water/toluene (90/5/5, v/v). It was found that the recovery of the hydrophobic pesticides improved with the addition of a small amount of toluene. Without the inclusion of toluene some of the hydrophobic pesticides remained in the lipid layer and did not partition efficiently into the more polar extraction solvent. Most compounds were found to have a recovery value in the range of 70-120%. A few polar compounds, such as acephate, exhibited low but reproducible (<10% RSD) recovery. Increasing the polarity of the extraction solvent may improve the recovery of these pesticides. Alternatively, the use of a suitable isotopically labelled internal standard can also be used to correct for any discrepancy in recovery.

GC-MS (full scan) analysis showed significant removal of lipids and other high molecular weight matrix coextractives using the LipiFiltr® cartridge, with no significant negative effect on CBD. This was backed up by LC-DAD analysis (not detailed here). While further work should be completed on other oil-based products, including those with a high THC content, the results highlighted here demonstrate that the LipiFiltr® cartridge can be successfully used to remove matrix coextractives from oil-based cannabis samples without compromising CBD content or pesticide recoveries.

^{**} Acequinocyl is unstable and degrades to acequinocyl-hydroxy.

^{***} Daminozide is a highly polar molecule that is difficult to incorporate in a multi-residue method (sample extraction & HPLC separation).
